

HW07 SCREENSHOTS AND EXPLANATIONS

EXPLANATIONS

Input_date.txt file will consist of dates in dd/MM/yyyy format, that include all days between a start and an end date entered by user. For example, if user enter 30/05/2015 as a start date and 30/05/2018 as an end date your function should generate all dates (day by day) between these two dates. To do this I make a function that includes if else statements to different conditions, for example your start year is equal to end year and start month is equal to end month or start year is equal to end year and start month is not equal to end month or start year is smaller than end year and much more. And then I open input_date.txt file and write days in this file.

Then, input_date.txt file, convert date format (dd/MM/yyyy) to (dddd, MMMM dd, yyyy) format and write this new formatted data into new_date.txt line by line. To do this I make a function that is compare the date that is in input_date.txt file with 01/01/1800 Wednesday date because I know that day is Wednesday. Firstly I take difference the year and 1800 and I find number of all leap years between them. Then I cross leap years 366 and remainder years 365. Then I find all number of days up to month of year that is in input_date.txt file. Then I add all values and result take mod by 7. Then I add mod on Wednesday. For example if mod is 1, date is Thursday. Then I write all days in new_date.txt file.
